## Patriot Missile System problem

- On February 25th, 1991, a Patriot Missile system at Dhahran, Saudi Arabia had failed to intercept a SCUD missile. The SCUD hit an Army Barracks, killing 28 Americans soldiers.
- Time is stored to an accuracy of 1/10th of a second in a 24-bit register.
- The error of representing 1/10th s in 24-bit register is 0.000000095 decimal.
- After 100 hr of operation, cumulative error gives  $0.000000095 \times 100 \times 60 \times 60 \times 10 = 0.34$  s.
- A SCUD travels at about 1,676 meters per second. In 0.34 s, it travels more than half a kilometer.

# Integers

## Unsigned integers

- An N-bit binary word can represent a total of  $2^N$  separate values.
- Range: 0 to  $2^N - 1$
- $$n_{10} = 2^{N-1}b_{N-1} + 2^{N-2}b_{N-2} + \dots + 2^1b_1 + 2^0b_0$$

## 2's complement signed integers

- Range:  $-2^{N-1}$  to  $2^{N-1} - 1$ .
- $$n_{10} = -b_{N-1}2^{N-1} + \sum_{i=0}^{N-2} b_i 2^i$$

in C:

- 8 bits (`char`, `int8_t`): [-128, 127]]
- 16 bits (`short`, `int16_t`): [-32768, 32767]
- 32 bits (`int`, `long`, `int32_t`): [-2147483648, 2147483647]

Bit Pattern	Unsigned	2's Complement
0000 0000	0	0
0000 0001	1	1
0000 0010	2	2
•	•	•
•	•	•
0111 1110	126	126
0111 1111	127	127
1000 0000	128	-128
1000 0001	129	-127
•	•	•
•	•	•
1111 1110	254	-2
1111 1111	255	-1

## Fixed-point representation

In fixed-point representation, a real number  $x$  is represented by an integer  $X$  with  $N = m + n + 1$  bits, where

- $N$  is the wordlength.
- $m$  represents the number of integer bits (to the left of the binary point).
- $n$  represents the number of fractional bits (to the right of the binary point).
- The weights of bits to the right of the binary point are negative powers of 2:  $2^{-1} = \frac{1}{2}$ ,  $2^{-2} = \frac{1}{4}$  ... , etc.
- Precision:  $2^{-n}$ .
- Range:  $-2^m$  to  $2^m - 2^{-n}$ .
- $n_{10} = \sum_{i=0}^{m-1} b_i 2^i + \sum_{i=1}^n b_i 2^{-i}$

## Qm.n notation

This naming convention does not take the MSB of the number (sign bit) into account.  
For instance:

- Q0.15 (Q15)
  - 16 bits;
  - Range: -1 to 0.99996948;
  - Precision:  $1/32768$  ( $2^{-15}$ ).
- Q3.12
  - 16 bits;
  - Range: -8 to 7.9998;
  - Precision:  $1/4096$  ( $2^{-12}$ ).
- Q0.31 (Q31)
  - 32 bits;
  - Range: -1 to 0.999999999534339;
  - Precision:  $4.6566129e-10$  ( $2^{-31}$ ).

## Conversion to and from fixed point

Conversion from real to fixed-point number:

$$X := \text{round}(x \cdot 2^n)$$

Conversion from fixed-point to real number:

$$x := X \cdot 2^{-n}$$

Example: Represent  $x = 13.4$  using Q4.3 format

$$X = \text{round}(13.4 \cdot 2^3) = 107(01101011_2)$$

Example: Represent  $x = 0.052246$  using Q4.11 format

$$X = \text{round}(0.052246 \cdot 2^{11}) = 107(0000000001101011_2)$$

## Scale of representation

- There is no difference at the CPU level between a fractional and an integer representation.
- The difference is based on the concept of *scale*, which is almost completely in the head of the designer.
- Values represented in Qm.n notation can be seen as a signed integer simply multiplied by  $2^{-n}$ , the precision.
- In fact, the scale factor can be an arbitrary scale that is not a power of two.
- Example: 16-bit 2's complement numbers between 8000H and 7FFFH can represent decimal values between -5 and +5, where the scale factor is  $5/32768$  ( $5 * 2^{-15}$ ).

## Scale factor, examples

Format	Scaling factor ( )	Range in Hex (fractional value)
(1.15)	$2^{15} = 32768$	0x7FFF (0.99) → 0x8000 (−1)
(2.14)	$2^{14} = 16384$	0x7FFF (1.99) → 0x8000 (−2)
(3.13)	$2^{13} = 8192$	0x7FFF (3.99) → 0x8000 (−4)
(4.12)	$2^{12} = 4096$	0x7FFF (7.99) → 0x8000 (−8)
(5.11)	$2^{11} = 2048$	0x7FFF (15.99) → 0x8000 (−16)
(6.10)	$2^{10} = 1024$	0x7FFF (31.99) → 0x8000 (−32)
(7.9)	$2^9 = 512$	0x7FFF (63.99) → 0x8000 (−64)
(8.8)	$2^8 = 256$	0x7FFF (127.99) → 0x8000 (−128)
(9.7)	$2^7 = 128$	0x7FFF (511.99) → 0x8000 (−512)
(10.6)	$2^6 = 64$	0x7FFF (1023.99) → 0x8000 (−1024)
(11.5)	$2^5 = 32$	0x7FFF (2047.99) → 0x8000 (−2048)
(12.4)	$2^4 = 16$	0x7FFF (4095.99) → 0x8000 (−4096)
(13.3)	$2^3 = 8$	0x7FFF (4095.99) → 0x8000 (−4096)
(14.2)	$2^2 = 4$	0x7FFF (8191.99) → 0x8000 (−8192)
(15.1)	$2^1 = 2$	0x7FFF (16383.99) → 0x8000 (−16384)
(16.0)	$2^0 = 1(\text{Integer})$	0x7FFF (32767) → 0x8000h (−32768)

# Dynamic range

Dynamic range is defined as,

$$DR_{dB} = 20 \log_{10} \left( \frac{\text{largest possible word value}}{\text{smallest possible word value}} \right) \quad [\text{dB}]$$

For N-bit signed integers,

$$DR_{dB} = 20 \log_{10} \left[ \frac{2^{(N-1)} - 1}{1} \right] \quad [\text{dB}]$$

$$DR_{dB} \approx 20 [(N-1) \log_{10}(2)]$$

$$DR_{dB} \approx 20 \log_{10}(2) \cdot (N-1)$$

$$DR_{dB} \approx 6.02 \cdot (N-1) \quad [\text{dB}]$$

# Precision and Dynamic range examples

Format (N.M)		Largest positive value (0x7FFF)	Least negative value (0x8000)	Precision (0x0001)		DR(dB)

16	0	32767	-32768	1	2 <sup>-0</sup>	90,30873362

## How to determine the correct range

How much bits are needed to represent  $\text{INT\_MIN} \leq \alpha \leq \text{INT\_MAX}$  ?

$$N = \text{floor}(\log_2(\max([\text{INT\_MIN}, \text{INT\_MAX}])) + 2)$$

### MATLAB

```
❶ » INT_MIN = 15; INT_MAX = 15;
❷ » MAX = max( [ INT_MIN, INT_MAX ] );
❸ » BITS = (log2 ( MAX ) + 2 ); % Round towards + Inf
❹ » N = floor ( BITS );
❺ » N = 5.00
```

## Addition in 2's complement

- Adding two N-bits numbers can produce a N+1 bits result.
- The result will have the same numbers of fractional bits.
- Only the integer part can grow.
- The last two bits of the carry row show if overflow occurs.

$$\begin{array}{r}
 \boxed{11}111\ 111\ (\text{carry}) \\
 0000\ 1111\ (15) \\
 +\ 1111\ 1011\ (-5) \\
 \hline
 0000\ 1010\ (10)
 \end{array}$$

$$\begin{array}{r}
 \boxed{01}11\ (\text{carry}) \\
 0111\ (7) \\
 +\ 0011\ (3) \\
 \hline
 1010\ (-6)\ \underline{\text{invalid!}}
 \end{array}$$

# Overflow

- An **overflow** occurs in a when a result is greater than  $2^{N-1} - 1$  or lesser than  $-2^{N-1}$ .
- An overflow produces a **roll-over** (wrap).

# Overflow II

- A roll-over usually has catastrophic consequences on a process.
- Only happen when two very large positive operands, or two very large negative operands are added.
- It can never happen during the addition of a positive operand and a negative operand, whatever their magnitude.

## Longer word-length accumulator

- Saving the result in a  $N+1$  word avoids overflows.
- The general rule is the sum of  $m$  individual  $b$ -bit can require as many as  $b + \log_2(m)$ .
- Example: 256 8-bits words requires an accumulator whose word length is  $8 + \log_2(256) = 16$ .
- DSP processors usually have 40-bit accumulators.
- ¿How many sums are supported by a 40-bits accumulator for 16-bits numbers?

# Saturation

- To avoid a rollover, overflow is detected and the result is saturated to the most positive or most negative value that can be represented.
- This procedure is called **saturation arithmetic**.
- DSP processors allows the results to be saturated automatically in hardware (In TI DSP C5505, SATD Bit of ST1\_55 register).

Be aware of non-linearity!

## Multiplication in 2's complement

- The product of 2 N-bit numbers requires  $(2m + 1 + 2n)$  bits to contain all possible values.
- The 2 MSBits are always equal (extension sign bit).
- Therefore,  $2N-1$  bits are enough to store the result.
- A Q15 multiplication produces Q1.30 result.
- To transform the result into Q31 notation, it must be left-shifted by one bit.
- DSP processors have a special mode that allows its ALU to automatically perform the left shift when  $Q15 \times Q15$ .

	11110100	-3/16
Accumulator	11110100	
	<hr/>	
Data Memory	1.110	-1/4

# Underflow

- After multiplication,  $2N-1$  bits must be stored in a memory of  $N$ -bits word.
- An **underflow** occurs if a result is less than  $2^{-n}$ .
- Q0.3 precision is  $2^{-3} = \frac{1}{8}$ .

- What number should the multiplication result be?  $-\frac{1}{8}$  or  $-\frac{2}{8}$ ?
- In other words, what bits should be discarded from a multiplication result?

# Rounding schemes, truncation and roundoff

- Truncation:  $e = Q[x] - x$ ,  $-2^{-n} \leq e < 0$ ,  $\mu = -\frac{2^{-n}}{2}$ ,  $\sigma^2 = \frac{2^{-n}}{12}$ .
- Roundoff:  $e = Q[x + 0.5] - x$ ,  $-2^{-n}/2 < e \leq 2^{-n}/2$ ,  $\mu = 0$ ,  $\sigma^2 = \frac{2^{-n}}{12}$ .
- DSP processors manage truncation and roundoff automatically.

# Logical and Arithmetic shifts

- Multiplication: all bits are shifted left by one position.
- Division: all bits are shifted right by one position, however the sign bit must be preserved (**arithmetic shift**).
- Arithmetic shift  $\neq$  logical shift.

## Logical and Arithmetic shifts (2)

In DSP processors:

- ALU can perform logical shifts of 32-bit operands in one cycle, from 16 bits to the right, to 15 bits to the left.
- Sign extension is performed during shifts to the right, if the Sign Extension Mode control bit (in C5505, SXM) is set.
- Result is saturated during shifts to the left if an overflow is detected, and Overflow bit (in C5505, OVM) is set.

# Accumulator

- DSP processors have an accumulator with extra bits to avoid overflow during internal calculations (in C5505, 40-bits accumulator).
- Guard bits: extra bits to avoid addition overflows.
- After MAC operations, only final result is adjusted to memory data size.
